Quick Question

Quick Question

0/2 points (graded)

In the previous video, we set up an optimization problem with 2 different types of tickets.

How many decision variables would we have if there were 4 different types of tickets?

16 ✖ **Answer:** 4

16

How many constraints would we have if there were 4 different types of tickets (with two different types of tickets, our model has 5 constraints: one capacity constraint, two demand constraints, and two non-negativity constraints)?

25 ✖ **Answer:** 9

25

Explanation

If our model had 4 different types of tickets, we would have four decision variables,

one for each type of ticket. We would have 9 constraints, since we would need one capacity constraint, 4 demand constraints, and 4 non-negativity constraints.
